

PLF LOAD DEVELOPMENT

CASE ONE: FLUSH BEAM

Typical **FLUSH BEAM** Framing

STEP 1 Determine the Trib Width (expressed in units of feet). In the example above, the Trib Width = 19'.

STEP 2 Determine the Live Load PLF and Total Load PLF on the Beam:
 $PLF_{LL} = (PSF_{LL}) \times (\text{Trib Width})$. Here, $PLF_{LL} = 40PSF \times 19' = 760 PLF_{LL}$
 $PLF_{TL} = (PSF_{TL}) \times (\text{Trib Width})$. Here, $PLF_{TL} = 50PSF \times 19' = 950 PLF_{TL}$

STEP 3 Use the appropriate PLF Table, (pages 48 – 59) and match the span of the LVL beam with the left "Span" column of the table. Always round the beam span up to the next whole foot. In this example use the Floor Table on page 48 with a span of 14':

STEP 4 Going from left to right, find a beam that supports a LL equal to or greater than 760 plf and a TL equal to or greater than 950 plf. Both checks must be made to properly size the beam.

STEP 5 A 2 ply 14" RIGIDLAM LVL will work ($778 > 760$ and $980 > 950$) but a 3 ply 11 $\frac{7}{8}$ " comes close. To check if the 3 ply 11 $\frac{7}{8}$ " LVL works at the actual span of 13'-6", interpolate the table between 13' and 14'. If you are not familiar with this, use a triangle as shown to the right to set up the proportion as follows:

FOR LL $(? - 712) / (14 - 13.5) = (889 - 712) / (14 - 13)$ or $(? - 712) / 0.5 = 177 / 1$ or $? = 800 \text{ plf LL} > 760 \text{ plf OK}$

The PLF value for TL at 14' is 1052 plf and since this is greater than the required 950 plf, interpolation is not required for total load.

An alternative solution would be a 3 ply 11 $\frac{7}{8}$ " RIGIDLAM LVL ($800 > 760$ and $1052 > 950$)

TRIB WIDTH for RIGIDLAM LVL Beam = $18'/2 + 20'/2 = 19'$ *

*** POWER TIP** For Flush Beams, the Trib Width = $38'/2 = 19'$ no matter where the Flush LVL Beam is located

HANGERS supporting I-Joists

JOISTS at any on-center spacing (it does not matter)

CASE TWO: DROPPED BEAM

Typical **DROPPED BEAM** Framing

If both spans of the I-joist are equal, there is 25% more load put into the LVL beam. If both spans are not equal, like shown in the diagram to the right (Span B > Span A), there is even more load placed into the LVL beam. The exact formula is complicated but fortunately there is a simple and safe way to size the LVL beam:

STEP 1 Assume both spans of the I-joist to be the longest span. In the example to the left, this would be Span B (21.25 ft).

STEP 2 Calculate the PLF on the LVL beam as if it were flush and increase by 25%:

$PLF_{LL} = 40PSF \times 21.25' \times 1.25 = 1063 PLF_{LL}$
 $PLF_{TL} = 50PSF \times 21.25' \times 1.25 = 1329 PLF_{TL}$

STEP 3 Use the longest span of the LVL beam (round up to the next whole foot) and use the appropriate PLF table. In this example, use a span of 17' and the table on page 50. Use a 3 ply 2.0E 16" RIGIDLAM LVL beam ($1081 > 1063$ & $1425 > 1329$).

When the LVL beam is dropped and the I-joists are continuous over the beam, there is more load transferred to the beam. This is because the continuous I-joist increase the trib width of the beam (green shaded area).

POST

DROPPED 2.0E RIGIDLAM LVL BEAM under continuous I-joists

This method will always be safe provided the long span of the I-joist (Span B) is not more than 5 times longer than the shorter span (Span A). When possible, RFP-KeyBeam™ sizing software should be used.
